Nearly 7 million Americans are living with Alzheimer’s, and many more are at risk of developing it or another dementia.

- A recent systematic review found 16.6% of individuals aged 65 and older have mild cognitive impairment (MCI). Studies indicate that one-third of them will develop dementia within 5 years.

- Nearly 10% of Americans aged 45 and older have subjective cognitive decline (SCD) — self-reported thinking or memory problems that are happening more often or getting worse. SCD is an early warning sign of possible future dementia.

- By 2060, the number of older adults with Alzheimer’s is projected to total nearly 14 million.

While treatments may slow the progression of cognitive decline, steps can be taken now to reduce the risk of developing it.

- Traumatic brain injury increases the risk of developing certain forms of dementia.

- Addressing cardiovascular health — mid-life hypertension, diabetes, smoking, mid-life obesity, and physical activity — can reduce the risk of cognitive decline and possibly dementia.

- Poor sleep quality and sleep disorders increases the risk of cognitive decline and possibly dementia.

- A balanced diet and cognitive engagement may reduce the risk of cognitive decline.

What Can Public Health Do?

- Embed cognitive decline risk factors into evidence-informed health promotion and chronic disease prevention awareness and education campaigns.

- Engage diverse audiences to develop culturally responsive messaging about brain health.

- Engage with communities, especially those at highest risk, about risk factors for dementia.

- Train current and future public health professionals about risk factors for cognitive decline and dementia, including ways to integrate this information with other chronic disease prevention strategies.

- Provide policymakers with information on risk factors, and offer evidence-informed policy options to address them.

However, these gains may evaporate in the future.

- With the growth in the rates of diabetes and obesity in the United States, any improvement in dementia prevalence and incidence rates could be erased in the future.

- Additionally, the prevalence of hypertension remains high — affecting nearly half of U.S. adults — and on average, less than one-fifth of adults with hypertension have their condition aggressively controlled (systolic blood pressure < 120 mmHg).

- The consequence is that addressing possible risk factors for cognitive decline and dementia may be necessary not only to reduce the occurrence of dementia in the population but just to prevent the current projections from getting worse.
